# **SQL Basics Cheat Sheet**

### SQL

**SQL**, or Structured Query Language, is a language to talk to databases. It allows you to select specific data and to build complex reports. Today, SQL is a universal language of data. It is used in practically all technologies that process data.

#### SAMPLE DATA

COUNTRY					
id	na	me	pop	ulation	area
1	Fra	nce	66	600000	640680
2	Gerr	many	86	700000	357000
•••	•	••		•••	•••
CITY					
id	name	countr	y_id	population	on rating
1	Paris	1		2243000	5
2	Berlin	2		3460000	3
	•••				•••

## **QUERYING SINGLE TABLE**

Fetch all columns from the country table:

```
SELECT *
FROM country;
```

Fetch id and name columns from the city table:

```
SELECT id. name
FROM city;
```

Fetch city names sorted by the rating column in the default ASCending order:

```
SELECT name
FROM city
ORDER BY rating [ASC];
```

Fetch city names sorted by the rating column in the DESCending order:

```
SELECT name
FROM city
ORDER BY rating DESC;
```

## **ALIASES**

#### **COLUMNS**

SELECT name AS city\_name FROM city;

#### **TABLES**

SELECT co.name, ci.name FROM city AS ci JOIN country AS co ON ci.country\_id = co.id;

### FILTERING THE OUTPUT

### **COMPARISON OPERATORS**

Fetch names of cities that have a rating above 3:

```
SELECT name
FROM city
WHERE rating > 3;
```

Fetch names of cities that are neither Berlin nor Madrid:

```
SELECT name
FROM city
WHERE name != 'Berlin'
  AND name != 'Madrid';
```

#### **TEXT OPERATORS**

**OTHER OPERATORS** 

500K and 5M:

FROM city

SELECT name

SELECT name

SELECT name

FROM city

FROM city

Fetch names of cities that start with a 'P' or end with an 's':

Fetch names of cities thttps://eduassistpro.github.io/ 'ublin' (like Dublin in Ir

Fetch names of cities that have a population between

Fetch names of cities that don't miss a rating value:

WHERE rating IS NOT NULL;

WHERE population BETWEEN 500000 AND 5000000;

Fetch names of cities that are in countries with IDs 1, 4, 7, or 8:

## **QUERYING MULTIPLE TABLES**

#### **INNER JOIN**

JOIN (or explicitly INNER JOIN) returns rows that have matching values in both tables.

```
SELECT city.name, country.name
FROM city
[INNER] JOIN country
 ON city.country id = country.id;
```

CITY			COUNTRY	
id	name	country_id	id	name
1	Paris	1	1	France
2	Berlin	2	2	Germany
3	Warsaw	4	3	Tceland

#### **FULL JOIN**

FULL JOIN (or explicitly FULL OUTER JOIN) returns all rows from both tables - if there's no matching row in the second table, **NULL**s are returned.

```
SELECT city.name, country.name
FROM city
FULL [OUTER] JOIN country
 ON city.country_id = country.id;
```

CITY			COUNTRY	
id	name	country_id	id	name
1	Paris	1	1	France
2	Berlin	2	2	Germany
3	Warsaw	4	NULL	NULL
NULL	NULL	NULL	3	Iceland

#### **CROSS JOIN**

**CROSS** JOIN returns all possible combinations of rows from both tables. There are two syntaxes available.

SELECT city.name, country.name FROM city CROSS JOIN country;

SELECT city.name, country.name FROM city, country;

CITY			COUNTRY	
id	name	country_id	id	name
1	Paris	1	1	France
1	Paris	1	2	Germany
2	Berlin	2	1	France
2	Berlin	2	2	Germany

## **RIGHT JOIN**

RIGHT JOIN returns all rows from the right table with corresponding rows from the left table. If there's no matching row, NULLs are returned as values from the left table.

SELECT city.name, country.name FROM city **RIGHT JOIN** country ON city.country\_id = country.id;

C	ITY			COUNTRY	
	id	name	country_id	id	name
	1	Paris	1	1	France
	2	Berlin	2	2	Germany
	NULL	NULL	NULL	3	Iceland

#### **NATURAL JOIN**

NATURAL JOIN will join tables by all columns with the same name.

SELECT city.name, country.name FROM city

NATURAL JOIN country;

CITY			COUNTRY	
country_id	id	name	name	id
6	6	San Marino	San Marino	6
7	7	Vatican City	Vatican City	7
5	9	Greece	Greece	9
10	11	Monaco	Monaco	10

NATURAL JOIN used these columns to match rows: city.id, city.name, country.id, country.name NATURAL JOIN is very rarely used in practice.

WHERE country\_id IN (1, 4, 7, 8);

## LearnSQL • com

#### AGGREGATION AND GROUPING

GROUP BY **groups** together rows that have the same values in specified columns. It computes summaries (aggregates) for each unique combination of values.

CITY		
id	name	country_id
1	Paris	1
101	Marseille	1
102	Lyon	1
2	Berlin	2
103	Hamburg	2
104	Munich	2
3	Warsaw	4
105	Cracow	4

#### **AGGREGATE FUNCTIONS**

- avg(expr) average value for rows within the group
- count(expr) count of values for rows within the group
- max(expr) maximum value within the group
- min(expr) minimum value within the group
- **sum(**expr**)** sum of values within the group

#### **EXAMPLE QUERIES**

Find out the number of cities:

```
SELECT COUNT(*)
FROM city;
```

Find out the number of cities with non-null ratings:

```
SELECT COUNT(rating)
FROM city;
```

Find out the number of distinctive country values:

```
SELECT COUNT(DISTINCT country_id)
FROM city;
```

Find out the smallest and the greatest country populations:

```
SELECT MIN(population), MAX(population)
FROM country;
```

Find out the total population of cities in respective countries:

```
SELECT country_id, SUM(population)
FROM city
GROUP BY country_id;
```

Find out the average rating for cities in respective countries if the average is above 3.0:

```
SELECT country_id, AVG(rating)
FROM city
GROUP BY country_id
HAVING AVG(rating) > 3.0;
```

### **SUBQUERIES**

A subquery is a query that is nested inside another query, or inside another subquery. There are different types of subqueries.

#### **SINGLE VALUE**

The simplest subquery returns exactly one column and exactly one row. It can be used with comparison operators =, <, <=, >, or >=.

This query finds cities with the same rating as Paris:

```
SELECT name FROM city
WHERE rating = (
    SELECT rating
    FROM city
    WHERE name = 'Paris'
);
```

#### **MULTIPLE VALUES**

 $A \, subquery \, can \, also \, return \, multiple \, columns \, or \, multiple \, rows. \, Such \, subqueries \, can \, be \,$ 

# used with operators IN EXIS DALL or ANY CATE TO SELECT THE SELECT

SELECT name

# https://eduassistpro.github.id

# Acceptate Gubque Variette he tall le introduce CU\_ass

query.

This query finds cities with a population greater than the average population in the country:

```
SELECT *
FROM city main_city
WHERE population > (
    SELECT AVG(population)
    FROM city average_city
    WHERE average_city.country_id = main_city.country_id
);
```

This guery finds countries that have at least one city:

```
SELECT name
FROM country
WHERE EXISTS (
    SELECT *
    FROM city
    WHERE country_id = country.id
);
```

#### SET OPERATIONS

Set operations are used to combine the results of two or more queries into a single result. The combined queries must return the same number of columns and compatible data types. The names of the corresponding columns can be different.

CYCLING		
id	name	country
1	YK	DE
2	ZG	DE
3	WT	PL

SKATING		
id	name	countr
1	YK	DE
2	DF	DE
3	AK	PL

#### **UNION**

UNION combines the results of two result sets and removes duplicates.
UNION ALL doesn't remove duplicate rows.

This query displays German cyclists together with German skaters:

```
SELECT name
Country = 'DE'
UNION / UNION ALL
SELECT name
FROM skating
WHERE country = 'DE'
INTERSECT
```

INTERSECT returns only rows that appear in both result sets.

This query displays German cyclists who are also German skaters at the same time:

```
FROM cycling
WHERE country = 'DE'
INTERSECT
SELECT name
FROM skating
WHERE country = 'DE';
```

#### **EXCEPT**

EXCEPT returns only the rows that appear in the first result set but do not appear in the second result set.

This query displays German cyclists unless they are also German skaters at the same time:

```
SELECT name
FROM cycling
WHERE country = 'DE'
EXCEPT / MINUS
SELECT name
FROM skating
WHERE country = 'DE';
```
